(54) **Stabilizer mixtures for organic materials**

(57) Organic materials which possess outstanding stability to oxidative, thermal or light-induced degradation comprise as stabilizers at least one compound of the benzofuran-2-one type and at least one compound of the sterically hindered amine type.

An organic phosphite or phosphonite may also be included in the stabilizer mixture.

The organic material may be a polymer e.g. a polyolefin, for instance phenol-free polyolefin fibre.

**GB 2 315 070 A**

Phenol-free stabilization of polyolefin fibres

The present invention relates to compositions comprising an organic material subject to oxidative, thermal or light-induced degradation, especially polyolefins, for example polyolefin fibres, and as stabilizers at least one compound of the benzofuran-2-one type and at least one compound of the sterically hindered amine type, and to the use thereof for stabilizing organic materials against oxidative, thermal or light-induced degradation.

The use of compounds of the benzofuran-2-one type as stabilizers for organic polymers is known, for example, from US 4,325,863; US 4,388,244; US 5,175,312; US 5,252,643; US 5,216,052; US 5,369,159; US 5,488,117; US 5,356,966; US 5,367,008; US 5,428,162; US 5,428,177 or US 5,516,920.

Sterically hindered amines, including in particular compounds containing 2,2,6,6-tetramethylpiperidyl groups, are known as "hindered amine" light stabilizers (HALS).

The known stabilizers do not satisfy in every respect the high requirements which a stabilizer is required to meet, especially with regard to shelf life, water absorption, sensitivity to hydrolysis, in-process stabilization, colour properties, volatility, migration behaviour, compatibility and improvement in protection against light. As a result there continues to be a need for effective stabilizers for organic materials, especially polyolefins, for example polyolefin fibres, that are sensitive to oxidative, thermal and/or light-induced degradation.

Polyolefin fibres have to date been stabilized with sterically hindered phenols in combination with compounds from the group of the organic phosphites or phosphonites and, in some cases, with additional use of light stabilizers. The use of such stabilizer mixtures leads in many cases to yellowing of the polyolefin fibres thus produced, especially under the action of NO<sub>x</sub> gas, referred to in the art as gas fading. In many cases discoloration occurs even during processing, especially in the case of melt extrusion. It is also known that compounds from the group of the sterically hindered amines, which may be added as light stabilizers, show an antagonistic effect together with the sterically hindered phenols, which adversely affects the long-term thermal stability.

It has now been found that a stabilizer mixture comprising at least one compound of the benzofuran-2-one type and at least one compound of the sterically hindered amine type is particularly suitable as a stabilizer for organic materials which are sensitive to oxidative, thermal or light-induced degradation. Such phenol-free stabilization systems exhibit, in particular, excellent stabilization of polyolefins in the course of processing to polypropylene fibres, for example. These novel stabilizer systems suppress the discoloration of the organic materials during processing, have an excellent action in respect of resistance to the effect of  $\text{NO}_x$  (no gas fading) and, moreover, exhibit improved long-term thermal stability relative to stabilization systems which include phenolic antioxidants. The sterically hindered amines, which replace the phenolic long-term thermal stabilizers, additionally provide good protection against photooxidative degradation of the organic material.

The present invention therefore provides compositions comprising

- a) an organic material which is subject to oxidative, thermal or light-induced degradation,
- b) at least one compound of the benzofuran-2-one type, and
- c) at least one compound of the sterically hindered amine group.

The present invention also provides compositions comprising, in addition to components (a), (b) and (c), also d) at least one compound from the group of the organic phosphites or phosphonites.

The mixture of components (b) and (c) or (b), (c) and (d) is likewise used for polyurethane production, especially for preparing flexible polyurethane foams. In this context the novel compositions and the products produced therefrom are effectively protected against degradation. In particular, scorching during foam production is avoided.

The polyurethanes are obtained, for example, by reacting polyethers, polyesters and polybutadienes which contain terminal hydroxyl groups with aliphatic or aromatic polyisocyanates.

Polyethers having terminal hydroxyl groups are known and are prepared, for example, by polymerizing epoxides such as ethylene oxide, propylene oxide, butylene oxide, tetrahydrofuran, styrene oxide or epichlorohydrin with themselves, for example in the presence of  $\text{BF}_3$ , or by addition reaction of these epoxides, alone or as a mixture or in succession, with starting components containing reactive hydrogen atoms, such as water, alcohols, ammonia or amines, for example ethylene glycol, propylene 1,3- and 1,2-glycol, trimethylolpropane, 4,4'-dihydroxydiphenylpropane, aniline, ethanolamine or

ethylenediamine. Sucrose polyethers are also suitable in accordance with the invention. In many cases preference is given to those polyethers which predominantly (up to 90 % by weight, based on all the OH groups present in the polyether) contain primary OH groups. Furthermore, polyethers modified by vinyl polymers, as are formed, for example, by polymerizing styrene and acrylonitrile in the presence of polyethers, are suitable, as are polybutadienes containing OH groups.

These compounds generally have molecular weights of 40 and are polyhydroxy compounds, especially compounds containing from two to eight hydroxyl groups, especially those of molecular weight from 800 to 10 000, preferably from 1000 to 6000, for example polyethers containing at least 2, generally 2 to 8, but preferably 2 to 4, hydroxyl groups, as are known for the preparation of homogeneous polyurethanes and cellular polyurethanes.

It is of course possible to employ mixtures of the above compounds containing at least two isocyanate-reactive hydrogen atoms, in particular with a molecular weight of 400 - 10 000.

Suitable polyisocyanates are aliphatic, cycloaliphatic, araliphatic, aromatic and heterocyclic polyisocyanates, for example ethylene diisocyanate, 1,4-tetramethylene diisocyanate, 1,6-hexamethylene diisocyanate, 1,12-dodecane diisocyanate, cyclobutane 1,3-diisocyanate, cyclohexane 1,3- and -1,4-diisocyanate and also any desired mixtures of these isomers, 1-isocyanato-3,3,5-trimethyl-5-isocyanatomethylcyclohexane, 2,4- and 2,6-hexahydrotolylene diisocyanate and also any desired mixtures of these isomers, hexahydro-1,3- and/or -1,4-phenylene diisocyanate, perhydro-2,4'- and/or -4,4'-diphenylmethane-diisocyanate, 1,3- and 1,4-phenylene diisocyanate, 2,4- and 2,6-tolylene diisocyanate, and also any desired mixtures of these isomers, diphenylmethane 2,4'- and/or -4,4'-diisocyanate, naphthylene 1,5-diisocyanate, triphenylmethane 4,4',4"-triisocyanate, polyphenyl-polymethylene polyisocyanates as are obtained by aniline-formaldehyde condensation followed by phosgenization, m- and p-isocyanatophenylsulfonyl isocyanates, perchlorinated aryl polyisocyanates, polyisocyanates containing carbodiimide groups, polyisocyanates containing allophanate groups, polyisocyanates containing isocyanurate groups, polyisocyanates containing urethane groups, polyisocyanates containing acylated urea groups, polyisocyanates containing biuret groups, polyisocyanates containing ester groups, reaction products of the abovementioned isocyanates with acetals, and polyisocyanates containing polymeric fatty acid radicals.

It is also possible to employ the isocyanate group-containing distillation residues, as they are or dissolved in one or more of the abovementioned polyisocyanates, which are obtained in the course of the industrial preparation of isocyanates. It is additionally possible to use any desired mixtures of the abovementioned polyisocyanates.

Particular preference is given in general to the polyisocyanates which are readily obtainable industrially, for example 2,4- and 2,6-tolylene diisocyanate and any desired mixtures of these isomers ("TDI"), polyphenyl-polymethylene-polyisocyanates as prepared by aniline-formaldehyde condensation followed by phosgenization ("crude MDI"), and polyisocyanates containing carbodiimide, urethane, allophanate, isocyanurate, urea or biuret groups ("modified polyisocyanates").

The organic materials to be protected are preferably natural, semisynthetic or preferably synthetic polymers. Particular preference is given to thermoplastic polymers, especially polyolefins, in particular polyethylene and polypropylene or copolymers thereof with mono- and diolefins. Particular preference is given to a polyolefin fibre, especially an essentially phenol-free polyolefin fibre.

The term essentially phenol-free polyolefin fibre denotes that the amount of phenolic antioxidants is less than 0.02 % based on the weight of the polyolefin fibre to be stabilized. These small amounts of phenolic antioxidants are added by the polyolefin manufacturers during preparation in order to provide initial stabilization of the polyolefins.

Particular emphasis is to be placed on the action of the novel components (b) and (c) or (b), (c) and (d) against thermal and oxidative degradation, especially under thermal stress as occurs during the processing of thermoplastics. The novel components (b) and (c) or (b), (c) and (d) are therefore outstandingly suitable for use as in-process stabilizers.

The mixture of components (b) and (c) or (b), (c) and (d) is also suitable for stabilizing polyolefins which are in long-term contact with extracting media.

Component (b) is preferably added to the organic material to be stabilized in an amount of from 0.0005 to 5 %, in particular from 0.001 to 2 %, for example from 0.01 to 2 %, based on the weight of the organic material to be stabilized.

Components (c) and (d) are judiciously added to the organic material to be stabilized in an amount of from 0.01 to 10 %, for example from 0.01 to 5 %, preferably from 0.025 to 3 % and, in particular, from 0.025 to 1 %, based on the weight of the organic material to be stabilized.

In addition to components (a), (b), (c) and (d) the novel compositions may comprise further costabilizers (additives) such as, for example, the following:

The costabilizers are added, for example, in concentrations of from 0.01 to 10 %, based on the overall weight of the organic material to be stabilized.

The fillers and reinforcing agents (item 12 in the list), for example talc, calcium carbonate, mica or kaolin, are added to the polyolefins in concentrations, for example, of from 0.01 to 40 %, based on the overall weight of the polyolefins to be stabilized.

The fillers and reinforcing agents (item 12 in the list), for example metal hydroxides, especially aluminium hydroxide or magnesium hydroxide, are added to the polyolefins in

concentrations, for example, of from 0.01 to 60 %, based on the overall weight of the polyolefins to be stabilized.

Glass fibers as reinforcing agents are added to the polyolefins in concentrations, judiciously, of from 0.01 to 20 %, based on the overall weight of the polyolefins to be stabilized.

Further preferred compositions comprise in addition to components (a) to (d) further additives as well, especially alkaline earth metal salts of higher fatty acids, for example calcium stearate.

As a conventional stabilizer combination for processing polymeric organic materials, for example polyolefins, to form corresponding mouldings, the combination of a phenolic antioxidant with a secondary antioxidant based on an organic phosphite or phosphonite is recommended. Depending on the particular substrate and process, however, many polyolefin processors are forced to operate processes in the high-temperature region above about 280°C. By virtue of the incorporation of a novel processing stabilizer mixture of components (b) and (c) or (b), (c) and (d), which is specially suitable for high-temperature applications, in particular in the temperature range above 300°C, industrial materials and mouldings, based for instance on high-density polyethylene, for example pipes and their technical variants (fittings), can be produced at a greater rate and with fewer rejects. Another advantage of this stabilizer mixture is that it can be employed in very small amounts. This leads to a reduction in the overall concentration of antioxidant relative to conventional stabilizer mixtures. Thus the use of a low concentration of a stabilizer of the benzofuran-2-one type [component (b)] allows a reduction in the overall concentration of stabilizer by about a third in polyolefins, for example, which simultaneously represent an economic advantage.

The incorporation of components (b) and (c) or (b), (c) and (d), and further additives if desired, into the polymeric, organic material is carried out by known methods, for example prior to or during shaping or else by applying the dissolved or dispersed stabilizer mixture to

the polymeric organic material, with or without subsequent evaporation of the solvent. The stabilizer mixture of components (b) and (c) or (b), (c) and (d) with or without further additives, can also be added in the form of a master batch, which contains these components in a concentration, for example, of from 2.5 to 25 % by weight, to the materials that are to be stabilized.

The stabilizer mixture of components (b) and (c) or (b), (c) and (d), with or without further additives, can also be added before or during polymerization or prior to crosslinking.

The stabilizer mixture of components (b) and (c) or (b), (c) and (d), with or without further additives, can be incorporated in pure form or encapsulated in waxes, oils or polymers into the organic material that is to be stabilized.

The stabilizer mixture of components (b) and (c) or (b), (c) and (d), with or without further additives, can also be sprayed onto the polymer that is to be stabilized. It is able to dilute other additives (for example the conventional additives indicated above) or their melts so that they too can be sprayed together with these additives onto the polymer that is to be stabilized. Addition by spraying on during the deactivation of the polymerization catalysts is particularly advantageous, it being possible to carry out spraying using, for example, the steam used for deactivation.

In the case of spherically polymerized polyolefins it may, for example, be advantageous to apply the stabilizer mixture of components (b) and (c) or (b), (c) and (d), with or without other additives, by spraying.

The materials stabilized in this way can be employed in a wide variety of forms, for example as films, fibres, tapes, moulding compositions, as profiles or as binders for coating materials, especially powder coatings, adhesives or putties.

The polyolefins stabilized in this way can likewise be employed in a wide variety of forms, especially as thick-layer polyolefin mouldings which are in long-term contact with extractive media, such as, for example, pipes for liquids or gases, films, fibres, geomembranes, tapes, profiles or tanks.

The preferred thick-layer polyolefin mouldings have a layer thickness of from 1 to 50 mm, in particular from 1 to 30 mm, for example from 2 to 10 mm.

As already mentioned, the organic materials to be protected are preferably organic, especially synthetic, polymers. In this context, thermoplastic materials are protected with particular advantage. Attention should be drawn above all in this context to the outstanding activity of the novel stabilizer mixture of components (b) and (c) or (b), (c) and (d) as in-process stabilizers (heat stabilizers). For this purpose they are advantageously added to the polymer prior to or during its processing. However, other polymers too (for example elastomers) or lubricants or hydraulic fluids can be stabilized against degradation, for example light-induced or thermooxidative degradation. Elastomers can be taken from the above listing of possible organic materials.

The lubricants and hydraulic fluids in question are based, for example, on mineral oils or synthetic oils or on mixtures thereof. The lubricants are familiar to the skilled worker and are described in the relevant technical literature, for example in Dieter Klamann, "Schmierstoffe und verwandte Produkte" (Verlag Chemie, Weinheim, 1982), in Schewe-Kobek, "Das Schmiermittel-Taschenbuch" (Dr. Alfred Hüthig-Verlag, Heidelberg, 1974) and in "Ullmanns Enzyklopädie der technischen Chemie", Vol.13, pages 85-94 (Verlag Chemie, Weinheim, 1977).

A preferred embodiment of the present invention is therefore the use of components (b) and (c) or (b), (c) and (d) as stabilizers, especially in-process stabilizers (thermal stabilizers), for organic materials, especially thermoplastic polymers, against oxidative, thermal or light-induced degradation.

The present invention also relates to a stabilizer mixture comprising (i) at least one compound of the benzofuran-2-one type and (ii) at least one compound from the group of the sterically hindered amines.

The present invention likewise relates to a stabilizer mixture comprising (i) at least one compound of the benzofuran-2-one type, (ii) at least one compound from the group of the

sterically hindered amines, and (iii) at least one compound from the group of the organic phosphites or phosphonites.

Preference is also given to stabilizer mixtures in which the weight ratio of the components (i) : (ii) is from 100 : 1 to 0.01 : 100, in particular from 5 : 1 to 0.01 : 10.

Preference is likewise given to stabilizer mixtures in which the weight ratio of the components (i) : (ii) : (iii) is from 100 : 1 : 0.01 to 0.01 : 1 : 100, in particular from 5 : 1 : 0.1 to 0.01 : 1 : 10.

The novel stabilizer mixtures of components (b) and (c) or (b), (c) and (d) feature excellent stability to hydrolysis and advantageous colour behaviour, i.e. little discoloration of the organic materials during processing.

Organic materials which are stabilized with the components of the present invention are particularly well protected against light-induced degradation.

The present invention also relates to a process for stabilizing an organic material against oxidative, thermal or light-induced degradation, which comprises incorporating in or applying to said material at least one each of components (b) and (c) or of components (b), (c) and (d).

Preference is given to a process for stabilizing polyolefins that are in long-term contact with extractive media, where the polyolefins are thick-layer polyolefin mouldings and have a layer thickness of from 1 to 50 mm, in particular from 1 to 30 mm, for example from 2 to 10 mm, which comprises incorporating in or applying to said polyolefins at least one each of components (b) and (c) or of (b), (c) and (d).

Also of particular interest is a process for stabilizing thick-layer polyolefin mouldings that are in long-term contact with extractive media, wherein the thick-layer polyolefin mouldings are pipes or geomembranes, which comprises incorporating in or applying to said mouldings at least one each of components (b) and (c) or of (b), (c) and (d).

The term geomembranes refers to films which are employed, for example, in landfill sites and are required to have a service life of up to 300 years.

Extractive media are, for example, liquid or gaseous inorganic or organic materials.

Examples of gaseous inorganic materials are oxygen; nitrogen; oxides of nitrogen; for example NO, laughing gas or NO<sub>2</sub>; oxides of sulfur, for example sulfur dioxide; halogens, for example fluorine or chlorine; Brönstedt acids, for example hydrofluoric acid, hydrochloric acid, hydrobromic acid, hydroiodic acid or hydrocyanic acid; or bases, for example ammonia.

Examples of gaseous organic materials are C<sub>1</sub>-C<sub>4</sub>alkanes, for example methane, ethane, propane or butane; carbon monoxide; carbon dioxide; or phosgene.

Examples of liquid inorganic materials are water, chlorinated drinking water or aqueous salt solutions, for example sodium chloride solution (brine) or sodium sulfate solution; bromine; acid halides, e.g. titanium tetrachloride, thionyl chloride, nitrosyl chloride or trimethylsilyl chloride; alkalis, for example aqueous sodium hydroxide (NaOH), aqueous potassium hydroxide (KOH), aqueous ammonia solution, aqueous sodium bicarbonate solution or aqueous sodium carbonate solution.

Examples of liquid organic materials are organic solvents or liquid organic reagents.

Examples of organic solvents are aliphatic hydrocarbons, for example pentane, hexane, heptane, octane, petroleum spirit, nonane or decane; alcohols, for example methanol, ethanol, isopropanol, butanol, pentanol, amyl alcohol, cyclohexanol, pentaerythritol, ethylene glycol, ethylene diglycol, methylcellosolve, polyethylene glycol or glycerol; ketones, for example acetone, diethyl ketone, methyl ethyl ketone, diphenyl ketone or cyclohexanone; ethers, for example diethyl ether, dibutyl ether, tetrahydrofuran or dioxane; aromatic hydrocarbons, for example benzene, toluene or xylene; heterocyclic solvents, for example furan, pyridine, 2,6-lutidine or thiophene; dipolar aprotic solvents, for example dimethylformamide, diethylacetamide or acetonitrile; or surfactants.

For the purposes of the present invention, extractive media are also mixtures and solutions, especially aqueous mixtures, emulsions or solutions, of liquid or gaseous inorganic and organic materials as listed above.

Of particular interest are those extractive media which are important in the chemical industry or in landfill sites.

A preferred embodiment of the present invention is therefore also the use of a stabilizer mixture of components (b) and (c) or of (b), (c) and (d), with or without further additives, for improving the stability of polyolefins that are in long-term contact with extractive media.

The preferred components (b) and (c) or (b), (c) and (d) for use as stabilizers, the process for stabilizing and the stabilizer mixture, are the same as those described for the compositions with an organic material.

The examples which follow illustrate the invention in more detail. Parts and percentages are by weight.

**Example 1:** Stabilizing polypropylene fibres processed at 250°C.

2.0 kg of polypropylene powder (B 10 FB<sup>®</sup> from Polychim S.A., France), which has a melt index of 12.0 g/dmin measured in accordance with DIN 53735 at 230°C and 2.16 kg, is homogenized with 0.05 % of calcium stearate and with the stabilizers indicated in Tables 1 and 2 for 2 minutes in a high-speed mixer. This mixture is extruded at 60 revolutions per minute in an extruder having a barrel diameter of 20 mm and a length of 400 mm, the three heating zones being set at the following temperatures: 200, 220 and 220°C. The extrudate is passed through a water bath for cooling and then granulated. These granules are processed to give a multifilament fibre. This is done using a single-screw extruder with a melt pump and a 37-hole spinning head. The maximum processing temperature is 250°C.

A portion of the unstretched fibre thus obtained is pressed for 6 minutes at 230°C to form a sheet with a thickness of 2 mm. The melt index (MFI, melt flow index) of this sheet is measured in accordance with DIN 53735 at 230°C and 2.16 kg. A large increase in the melt

index denotes severe chain degradation and thus poor stabilization. The results are compiled in Table 1.

Another portion of the unstretched fibre thus obtained is treated with a lubricant (Limanol®P 25, Schill und Seilacher, Böblingen, Germany) and subjected to preliminary drawing. This preliminary drawing leads to a fibre strand having a linear density of 416 g/90 m. This means that a fibre strand 90 m in length has a weight of 416 g. In a further operation, this fibre strand is again drawn at 120°C by a factor of 3.2 using a drawing apparatus. This leads to a fibre strand having a linear density of 130 g/90 m.

A portion of this fibre strand is used to produce a knitted tube. The yellowness index ( $YI_1$ ) of this knitted tube is determined in accordance with ASTM D 1925-77. Low  $YI_1$  values denote little discoloration, high  $YI_1$  values severe discoloration of the samples. The results are compiled in Table 1. This knitted tube is exposed in the presence of from 4 to 6 ppm nitrogen dioxide ( $NO_2$ ) at 40°C and 87 % relative atmospheric humidity for 48 hours in accordance with AATCC 164. The yellowness index ( $YI_2$ ) of this exposed knitted tube is determined in accordance with ASTM D 1925-77. Low  $YI_2$  values denote little discoloration, high  $YI_2$  values severe discoloration of the samples. The results are compiled in Table 1.

Another portion of the fibre strand is used to carry out an oven ageing test at 100°C. In this test, a measurement is made, in days, of the time taken for the fibre strand to tear under the test conditions. The longer the period before tearing of the fibre strand, the better the stabilization. The results are compiled in Table 2.

Another portion of the unstretched fibre is pressed for 6 minutes at 230°C to form a thin film with a thickness of 0.10 mm. This film is subjected to a Xenon test in accordance with DIN 53387. In this test, the film is exposed in a Xenon 1200 weathering apparatus until a carbonyl index of 0.25 is observed in the wavelength range from 1760 to 1680  $cm^{-1}$ . The larger the number, the better the stabilization. The results are compiled in Table 2.

Example 2: Stabilizing polypropylene fibres processed at 300°C.

2.0 kg of polypropylene powder (B 10 FB<sup>®</sup> from Polychim S.A., France), which has a melt index of 12.0 g/dmin measured in accordance with DIN 53735 at 230°C under 2.16 kg, is homogenized with 0.05 % of calcium stearate and with the stabilizers indicated in Tables 3 and 4 for 2 minutes in a high-speed mixer. This mixture is extruded at 60 revolutions per minute in an extruder having a barrel diameter of 20 mm and a length of 400 mm, the three heating zones being set at the following temperatures: 200, 220 and 220°C. The extrudate is passed through a water bath for cooling and then granulated. These granules are processed to give a multifilament fibre. This is done using a single-screw extruder with a melt pump and a 37-hole spinning head. The maximum processing temperature is 300°C.

A portion of the unstretched fibre thus obtained is pressed for 6 minutes at 230°C to form a sheet with a thickness of 2 mm. The melt index (MFI, melt flow index) of this sheet is measured in accordance with DIN 53735 at 230°C and 2.16 kg. A large increase in the melt index denotes severe chain degradation and thus poor stabilization. The results are compiled in Table 3.

Another portion of the unstretched fibre thus obtained is treated with a lubricant (Limanol<sup>®</sup>P 25, Schill und Seilacher, Böblingen, Germany) and subjected to preliminary drawing. This preliminary drawing leads to a fibre strand having a linear density of 416 g/90 m. This means that a fibre strand 90 m in length has a weight of 416 g. In a further operation, this fibre strand is again drawn at 120°C by a factor of 3.2 using a drawing apparatus. This leads to a fibre strand having a linear density of 130 g/90 m.

A portion of this fibre strand is used to produce a knitted tube. The yellowness index (YI<sub>1</sub>) of this knitted tube is determined in accordance with ASTM D 1925-77. Low YI<sub>1</sub> values denote little discoloration, high YI<sub>1</sub> values severe discoloration of the samples. The results are compiled in Table 3. This knitted tube is exposed in the presence of from 4 to 6 ppm nitrogen dioxide (NO<sub>2</sub>) at 40°C and 87 % relative atmospheric humidity for 48 hours in accordance with AATCC 164. The yellowness index (YI<sub>2</sub>) of this exposed knitted tube is determined in accordance with ASTM D 1925-77. Low YI<sub>2</sub> values denote little discoloration, high YI<sub>2</sub> values severe discoloration of the samples. The results are compiled in Table 3.

Another portion of the fibre strand is used to carry out an oven ageing test at 100°C. In this test, a measurement is made, in days, of the time taken for the fibre strand to tear under the test conditions. The longer the period before tearing of the fibre strand, the better the stabilization. The results are compiled in Table 4.

Another portion of the unstretched fibre is pressed for 6 minutes at 230°C to form a thin film with a thickness of 0.10 mm. This film is subjected to a Xenon test in accordance with DIN 53387. In this test, the film is exposed in a Xenon 1200 weathering apparatus until a carbonyl index of 0.25 is observed in the wavelength range from 1760 to 1680  $\text{cm}^{-1}$ . The larger the number, the better the stabilization. The results are compiled in Table 4.
